

Chapter 3

Introduction to Classes, Objects

Methods and Strings

Java™ How to Program, 10/e

OBJECTIVES

In this chapter you'll learn:

- How to declare a class and use it to create an object.
- How to implement a class's behaviors as methods.
- How to implement a class's attributes as instance variables.
- How to call an object's methods to make them perform their tasks.
- What local variables of a method are and how they differ from instance variables.
- What primitive types and reference types are.
- How to use a constructor to initialize an object's data.
- How to represent and use numbers containing decimal points.

3.1 Introduction

3.2 Instance Variables, set Methods and get Methods

- 3.2.1 **Account** Class with an Instance Variable, a *set* Method and a *get* Method
- 3.2.2 **AccountTest** Class That Creates and Uses an Object of Class **Account**
- 3.2.3 Compiling and Executing an App with Multiple Classes
- 3.2.4 **Account** UML Class Diagram with an Instance Variable and *set* and *get* Methods
- 3.2.5 Additional Notes on Class **AccountTest**
- 3.2.6 Software Engineering with **private** Instance Variables and **public** *set* and *get* Methods

3.3 Primitive Types vs. Reference Types

3.4 Account Class: Initializing Objects with Constructors

- 3.4.1 Declaring an **Account** Constructor for Custom Object Initialization
- 3.4.2 Class **AccountTest**: Initializing **Account** Objects When They're Created

3.5 Account Class with a Balance; Floating-Point Numbers

- 3.5.1 **Account** Class with a **balance** Instance Variable of Type **double**
- 3.5.2 **AccountTest** Class to Use Class **Account**

3.6 (Optional) GUI and Graphics Case Study: Using Dialog Boxes

3.7 Wrap-Up

3.2 Instance Variables, set Methods and get Methods

- ▶ Each class you create becomes a new type that can be used to declare variables and create objects.
- ▶ You can declare new classes as needed; this is one reason Java is known as an extensible language.

3.2.1 Account Class with an Instance Variable, a *set* Method and a *get* Method

```
1 // Fig. 3.1: Account.java
2 // Account class that contains a name instance variable
3 // and methods to set and get its value.
4
5 public class Account
6 {
7     private String name; // instance variable
8
9     // method to set the name in the object
10    public void setName(String name)
11    {
12        this.name = name; // store the name
13    }
14
15    // method to retrieve the name from the object
16    public String getName()
17    {
18        return name; // return value of name to caller
19    }
20 } // end class Account
```

Fig. 3.1 | Account class that contains a name instance variable and methods to set and get its value.

3.2.1 Account Class with an Instance Variable, a *set* Method and a *get* Method (Cont.)

Class Declaration

- ▶ Each class declaration that begins with the access modifier public must be stored in a file that has the same name as the class and ends with the .java filename extension.
- ▶ Every class declaration contains keyword class followed immediately by the class's name.

3.2.1 Account Class with an Instance Variable, a *set* Method and a *get* Method (Cont.)

Identifiers and Camel Case Naming

- ▶ Class, method and variable names are identifiers.
- ▶ By convention all use camel case names.
- ▶ Class names begin with an uppercase letter, and method and variable names begin with a lowercase letter.

3.2.1 Account Class with an Instance Variable, a *set* Method and a *get* Method (Cont.)

Instance Variable name

- ▶ An object has attributes that are implemented as instance variables and carried with it throughout its lifetime.
- ▶ Instance variables exist before methods are called on an object, while the methods are executing and after the methods complete execution.
- ▶ A class normally contains one or more methods that manipulate the instance variables that belong to particular objects of the class.
- ▶ Instance variables are declared inside a class declaration but outside the bodies of the class's method declarations.
- ▶ Each object (instance) of the class has its own copy of each of the class's instance variables.

Good Programming Practice 3.1

We prefer to list a class's instance variables first in the class's body, so that you see the names and types of the variables before they're used in the class's methods. You can list the class's instance variables anywhere in the class outside its method declarations, but scattering the instance variables can lead to hard-to-read code.

3.2.1 Account Class with an Instance Variable, a *set* Method and a *get* Method (Cont.)

Access Modifiers public and private

- ▶ Most instance-variable declarations are preceded with the keyword **private**, which is an access modifier.
- ▶ Variables or methods declared with access modifier **private** are accessible only to methods of the class in which they're declared.

3.1.1 Account Class with an Instance Variable, a *set* Method and a *get* Method (Cont.)

setName Method of Class Account

- ▶ Parameters are declared in a comma-separated parameter list, which is located inside the parentheses that follow the method name in the method declaration.
- ▶ Multiple parameters are separated by commas.
- ▶ Each parameter must specify a type followed by a variable name.

3.1.1 Account Class with an Instance Variable, a *set* Method and a *get* Method (Cont.)

Parameters Are Local Variables

- ▶ Variables declared in the body of a particular method are local variables and can be used only in that method.
- ▶ When a method terminates, the values of its local variables are lost.
- ▶ A method's parameters are local variables of the method.

3.1.1 Account Class with an Instance Variable, a *set* Method and a *get* Method (Cont.)

setName Method Body

- ▶ Every method's body is delimited by left and right braces ({ and }).
- ▶ Each method's body contains one or more statements that perform the method's task(s).

Good Programming Practice 3.2

We could have avoided the need for keyword `this` here by choosing a different name for the parameter in line 10, but using the `this` keyword as shown in line 12 is a widely accepted practice to minimize the proliferation of identifier names.

3.2.1 Account Class with an Instance Variable, a *set* Method and a *get* Method (Cont.)

getName Method of Class Account

- ▶ The method's return type specifies the type of data returned to a method's caller.
- ▶ Keyword `void` indicates that a method will perform a task but will not return any information.
- ▶ Empty parentheses following a method name indicate that the method does not require any parameters to perform its task.
- ▶ When a method that specifies a return type other than `void` is called and completes its task, the method must return a result to its calling method.

3.2.1 Account Class with an Instance Variable, a *set* Method and a *get* Method (Cont.)

- ▶ The return statement passes a value from a called method back to its caller.
- ▶ Classes often provide public methods to allow the class's clients to *set* or *get* private instance variables.
- ▶ The names of these methods need not begin with *set* or *get*, but this naming convention is recommended.

3.2.2 AccountTest Class That Creates and Uses an Object of Class Account

Driver Class AccountTest

- ▶ A class that creates an object of another class, then calls the object's methods, is a driver class.

```
1 // Fig. 3.2: AccountTest.java
2 // Creating and manipulating an Account object.
3 import java.util.Scanner;
4
5 public class AccountTest
6 {
7     public static void main(String[] args)
8     {
9         // create a Scanner object to obtain input from the command window
10        Scanner input = new Scanner(System.in);
11
12        // create an Account object and assign it to myAccount
13        Account myAccount = new Account();
14
15        // display initial value of name (null)
16        System.out.printf("Initial name is: %s%n%n", myAccount.getName());
17
18        // prompt for and read name
19        System.out.println("Please enter the name:");
20        String theName = input.nextLine(); // read a line of text
21        myAccount.setName(theName); // put theName in myAccount
22        System.out.println(); // outputs a blank line
23
```

Fig. 3.2 | Creating and manipulating an `Account` object. (Part 1 of 2.)

```
24     // display the name stored in object myAccount
25     System.out.printf("Name in object myAccount is:%n%s%n",
26             myAccount.getName());
27 }
28 } // end class AccountTest
```

Initial name is: null

Please enter the name:
Jane Green

Name in object myAccount is:
Jane Green

Fig. 3.2 | Creating and manipulating an `Account` object. (Part 2 of 2.)

3.2.2 AccountTest Class That Creates and Uses an Object of Class Account (Cont.)

Scanner Object for Receiving Input from the User

- ▶ Scanner method nextLine reads characters until a newline character is encountered, then returns the characters as a String.
- ▶ Scanner method next reads characters until any white-space character is encountered, then returns the characters as a String.

3.2.2 AccountTest Class That Creates and Uses an Object of Class Account (Cont.)

Instantiating an Object—Keyword new and Constructors

- ▶ A class instance creation expression begins with keyword new and creates a new object.
- ▶ A constructor is similar to a method but is called implicitly by the new operator to initialize an object's instance variables at the time the object is created.

3.2.2 AccountTest Class That Creates and Uses an Object of Class Account (Cont.)

Calling Class Account's getName Method

- ▶ To call a method of an object, follow the object name with a dot separator, the method name and a set of parentheses containing the method's arguments.

Error-Prevention Tip 3.1

Never use as a format-control a string that was input from the user. When method `System.out.printf` evaluates the format-control string in its first argument, the method performs tasks based on the conversion specifier(s) in that string. If the format-control string were obtained from the user, a malicious user could supply conversion specifiers that would be executed by `System.out.printf`, possibly causing a security breach.

3.2.2 AccountTest Class That Creates and Uses an Object of Class Account (Cont.)

null—the Default Initial Value for String Variables

- ▶ Local variables are not automatically initialized.
- ▶ Every instance variable has a default initial value—a value provided by Java when you do not specify the instance variable's initial value.
- ▶ The default value for an instance variable of type String is null.

3.2.2 AccountTest Class That Creates and Uses an Object of Class Account (Cont.)

Calling Class Account's setName Method

- ▶ A method call supplies values—known as arguments—for each of the method’s parameters.
- ▶ Each argument’s value is assigned to the corresponding parameter in the method header.
- ▶ The number of arguments in a method call must match the number of parameters in the method declaration’s parameter list.
- ▶ The argument types in the method call must be consistent with the types of the corresponding parameters in the method’s declaration.

3.2.3 Compiling and Executing an App with Multiple Classes

- ▶ The `javac` command can compile multiple classes at once.
- ▶ Simply list the source-code filenames after the command with each filename separated by a space from the next.
- ▶ If the directory containing the app includes only one app's files, you can compile all of its classes with the command `javac *.java`.
- ▶ The asterisk (*) in `*.java` indicates that all files in the current directory ending with the filename extension “`.java`” should be compiled.

3.2.4 Account UML Class Diagram with an Instance Variable and *set* and *get* Methods

Top Compartment

- ▶ In the UML, each class is modeled in a class diagram as a rectangle with three compartments. The top one contains the class's name centered horizontally in boldface.

Fig. 3.3 | UML class diagram for class **Account** of Fig. 3.1.

3.2.4 Account UML Class Diagram with an Instance Variable and *set* and *get* Methods (Cont.)

Middle Compartment

- ▶ The middle compartment contains the class's attributes, which correspond to instance variables in Java.

3.2.4 Account UML Class Diagram with an Instance Variable and *set* and *get* Methods (Cont.)

Bottom Compartment

- ▶ The bottom compartment contains the class's operations, which correspond to methods and constructors in Java.
- ▶ The UML represents instance variables as an attribute name, followed by a colon and the type.
- ▶ Private attributes are preceded by a minus sign (-) in the UML.
- ▶ The UML models operations by listing the operation name followed by a set of parentheses.
- ▶ A plus sign (+) in front of the operation name indicates that the operation is a public one in the UML (i.e., a public method in Java).

3.2.4 Account UML Class Diagram with an Instance Variable and *set* and *get* Methods (Cont.)

Return Types

- ▶ The UML indicates an operation's return type by placing a colon and the return type after the parentheses following the operation name.
- ▶ UML class diagrams do not specify return types for operations that do not return values.
- ▶ Declaring instance variables **private** is known as data hiding or information hiding.

3.2.4 Account UML Class Diagram with an Instance Variable and *set* and *get* Methods (Cont.)

Parameters

- ▶ The UML models a parameter of an operation by listing the parameter name, followed by a colon and the parameter type between the parentheses after the operation name

3.2.5 Additional Notes on Class AccountTest

static Method main

- ▶ You must call most methods other than `main` explicitly to tell them to perform their tasks.
- ▶ A key part of enabling the JVM to locate and call method `main` to begin the app's execution is the `static` keyword, which indicates that `main` is a `static` method that can be called without first creating an object of the class in which the method is declared.

3.2.5 Additional Notes on Class AccountTest (Cont.)

Notes on import Declarations

- ▶ Most classes you'll use in Java programs must be imported explicitly.
- ▶ There's a special relationship between classes that are compiled in the same directory.
- ▶ By default, such classes are considered to be in the same package—known as the default package.
- ▶ Classes in the same package are implicitly imported into the source-code files of other classes in that package.

3.2.5 Additional Notes on Class AccountTest (Cont.)

- ▶ An import declaration is not required when one class in a package uses another in the same package.
- ▶ An import- declaration is not required if you always refer to a class with its fully qualified class name, which includes its package name and class name.

Software Engineering Observation 3.1

The Java compiler does not require import declarations in a Java source-code file if the fully qualified class name is specified every time a class name is used. Most Java programmers prefer the more concise programming style enabled by import declarations.

3.2.6 Software Engineering with private Instance Variables and public *set* and *get* Methods

- ▶ Declaring instance variables **private** is known as data hiding or information hiding.

Software Engineering Observation 3.2

*Precede each instance variable and method declaration with an access modifier. Generally, instance variables should be declared **private** and methods **public**.*

*Later in the book, we'll discuss why you might want to declare a method **private**.*

3.2.7 Software Engineering with private Instance Variables and public *set* and *get* Methods

Fig. 3.4 | Conceptual view of an `Account` object with its encapsulated `private` instance variable `name` and protective layer of `public` methods.

3.3 Primitive Types vs. Reference Types

- ▶ Types in Java are divided into two categories—primitive types and reference types.
- ▶ The primitive types are boolean, byte, char, short, int, long, float and double.
- ▶ All other types are reference types, so classes, which specify the types of objects, are reference types.
- ▶ A primitive-type variable can store exactly one value of its declared type at a time.
- ▶ Primitive-type instance variables are initialized by default.
- ▶ Variables of types byte, char, short, int, long, float and double are initialized to 0.

3.3 Primitive Types vs. Reference Types (Cont.)

- ▶ Variables of type boolean are initialized to false.
- ▶ Reference-type variables (called references) store the location of an object in the computer's memory.
- ▶ Such variables refer to objects in the program.
- ▶ The object that's referenced may contain many instance variables and methods.
- ▶ Reference-type instance variables are initialized by default to the value null.
- ▶ A reference to an object is required to invoke an object's methods.
- ▶ A primitive-type variable does not refer to an object and therefore cannot be used to invoke a method.

3.4 Account Class: Initializing Objects with Constructors

- ▶ Each class you declare can optionally provide a constructor with parameters that can be used to initialize an object of a class when the object is created.
- ▶ Java *requires* a constructor call for *every* object that's created.

3.4.1 Declaring an Account Constructor for Custom Object Initialization

```
1 // Fig. 3.5: Account.java
2 // Account class with a constructor that initializes the name.
3
4 public class Account
5 {
6     private String name; // instance variable
7
8     // constructor initializes name with parameter name
9     public Account(String name) // constructor name is class name
10    {
11        this.name = name;
12    }
13
14    // method to set the name
15    public void setName(String name)
16    {
17        this.name = name;
18    }
19
20    // method to retrieve the name
21    public String getName()
22    {
23        return name;
24    }
25 } // end class Account
```

Fig. 3.5 | Account class with a constructor that initializes the name.

3.4.1 Declaring an Account Constructor for Custom Object Initialization (Cont.)

Error-Prevention Tip 3.2

Even though it's possible to do so, do not call methods from constructors. We'll explain this in Chapter 10, Object-Oriented Programming: Polymorphism and Interfaces.

3.4.2 Class AccountTest: Initializing Account Objects When They're Created

```
1 // Fig. 3.6: AccountTest.java
2 // Using the Account constructor to initialize the name instance
3 // variable at the time each Account object is created.
4
5 public class AccountTest
6 {
7     public static void main(String[] args)
8     {
9         // create two Account objects
10        Account account1 = new Account("Jane Green");
11        Account account2 = new Account("John Blue");
12
13        // display initial value of name for each Account
14        System.out.printf("account1 name is: %s%n", account1.getName());
15        System.out.printf("account2 name is: %s%n", account2.getName());
16    }
17 } // end class AccountTest
```

```
account1 name is: Jane Green
account2 name is: John Blue
```

Fig. 3.6 | Using the Account constructor to initialize the name instance variable at the time each Account object is created.

3.4.2 Class AccountTest: Initializing Account Objects When They're Created (Cont.)

Constructors Cannot Return Values

- ▶ Constructors can specify parameters but not return types.

Default Constructor

- ▶ If a class does not define constructors, the compiler provides a default constructor with no parameters, and the class's instance variables are initialized to their default values.

There's No Default Constructor in a Class That Declares a Constructor

- ▶ If you declare a constructor for a class, the compiler will *not* create a *default constructor* for that class.

Software Engineering Observation 3.3

Unless default initialization of your class's instance variables is acceptable, provide a custom constructor to ensure that your instance variables are properly initialized with meaningful values when each new object of your class is created.

3.4.2 Class AccountTest: Initializing Account Objects When They're Created (Cont.)

Adding the Constructor to Class Account's UML Class Diagram

- ▶ The UML models constructors in the third compartment of a class diagram.
- ▶ To distinguish a constructor from a class's operations, the UML places the word “constructor” between guillemets (« and ») before the constructor’s name.

Fig. 3.7 | UML class diagram for **Account** class of Fig. 3.5.

3.5 Account Class with a Balance; Floating-Point Numbers and Type `double`

- ▶ A floating-point number is a number with a decimal point.
- ▶ Java provides two primitive types for storing floating-point numbers in memory—`float` and `double`.
- ▶ Variables of type `float` represent single-precision floating-point numbers and have seven significant digits.
- ▶ Variables of type `double` represent double-precision floating-point numbers.
- ▶ These require twice as much memory as `float` variables and provide 15 significant digits—approximately double the precision of `float` variables.
- ▶ Floating-point literals are of type `double` by default.

3.5.1 Account Class with a balance Instance Variable of Type double

```
1 // Fig. 3.8: Account.java
2 // Account class with a double instance variable balance and a constructor
3 // and deposit method that perform validation.
4
5 public class Account
6 {
7     private String name; // instance variable
8     private double balance; // instance variable
9
10    // Account constructor that receives two parameters
11    public Account(String name, double balance)
12    {
13        this.name = name; // assign name to instance variable name
14
15        // validate that the balance is greater than 0.0; if it's not,
16        // instance variable balance keeps its default initial value of 0.0
17        if (balance > 0.0) // if the balance is valid
18            this.balance = balance; // assign it to instance variable balance
19    }
20}
```

Fig. 3.8 | Account class with a double instance variable balance and a constructor and deposit method that perform validation. (Part I of 3.)

```
21 // method that deposits (adds) only a valid amount to the balance
22 public void deposit(double depositAmount)
23 {
24     if (depositAmount > 0.0) // if the depositAmount is valid
25         balance = balance + depositAmount; // add it to the balance
26 }
27
28 // method returns the account balance
29 public double getBalance()
30 {
31     return balance;
32 }
33
34 // method that sets the name
35 public void setName(String name)
36 {
37     this.name = name;
38 }
39
```

Fig. 3.8 | Account class with a double instance variable balance and a constructor and deposit method that perform validation. (Part 2 of 3.)

```
40     // method that returns the name
41     public String getName()
42     {
43         return name; // give value of name back to caller
44     } // end method getName
45 } // end class Account
```

Fig. 3.8 | Account class with a double instance variable balance and a constructor and deposit method that perform validation. (Part 3 of 3.)

3.5.2 AccountTest Class to Use Class Account

```
1 // Fig. 3.9: AccountTest.java
2 // Inputting and outputting floating-point numbers with Account objects.
3 import java.util.Scanner;
4
5 public class AccountTest
6 {
7     public static void main(String[] args)
8     {
9         Account account1 = new Account("Jane Green", 50.00);
10        Account account2 = new Account("John Blue", -7.53);
11
12        // display initial balance of each object
13        System.out.printf("%s balance: $%.2f%n",
14                           account1.getName(), account1.getBalance());
15        System.out.printf("%s balance: $%.2f%n%n",
16                           account2.getName(), account2.getBalance());
17    }
}
```

Fig. 3.9 | Inputting and outputting floating-point numbers with `Account` objects.
(Part 1 of 4.)

```
18 // create a Scanner to obtain input from the command window
19 Scanner input = new Scanner(System.in);
20
21 System.out.print("Enter deposit amount for account1: "); // prompt
22 double depositAmount = input.nextDouble(); // obtain user input
23 System.out.printf("%nadding %.2f to account1 balance%n%n",
24 depositAmount);
25 account1.deposit(depositAmount); // add to account1's balance
26
27 // display balances
28 System.out.printf("%s balance: $%.2f%n",
29 account1.getName(), account1.getBalance());
30 System.out.printf("%s balance: $%.2f%n%n",
31 account2.getName(), account2.getBalance());
32
33 System.out.print("Enter deposit amount for account2: "); // prompt
34 depositAmount = input.nextDouble(); // obtain user input
35 System.out.printf("%nadding %.2f to account2 balance%n%n",
36 depositAmount);
37 account2.deposit(depositAmount); // add to account2 balance
38
```

Fig. 3.9 | Inputting and outputting floating-point numbers with `Account` objects.

(Part 2 of 4.)

```
39     // display balances
40     System.out.printf("%s balance: $%.2f%n",
41                     account1.getName(), account1.getBalance());
42     System.out.printf("%s balance: $%.2f%n%n",
43                     account2.getName(), account2.getBalance());
44 } // end main
45 } // end class AccountTest
```

```
Jane Green balance: $50.00
John Blue balance: $0.00
```

```
Enter deposit amount for account1: 25.53
```

```
adding 25.53 to account1 balance
```

```
Jane Green balance: $75.53
John Blue balance: $0.00
```

Fig. 3.9 | Inputting and outputting floating-point numbers with `Account` objects.
(Part 3 of 4.)

```
Enter deposit amount for account2: 123.45
```

```
adding 123.45 to account2 balance
```

```
Jane Green balance: $75.53
```

```
John Blue balance: $123.45
```

Fig. 3.9 | Inputting and outputting floating-point numbers with `Account` objects.
(Part 4 of 4.)

3.5.2 AccountTest Class to Use Class Account (Cont.)

- ▶ Scanner method nextDouble returns a double value.

3.5.2 AccountTest Class to Use Class Account (Cont.)

Formatting Floating-Point Numbers for Display

- ▶ The format specifier %f is used to output values of type float or double.
- ▶ The format specifier %.2f specifies that two digits of precision should be output to the right of the decimal point in the floating-point number.

3.5.2 AccountTest Class to Use Class Account (Cont.)

Common Programming Error 3.1

The Java compiler will issue a compilation error if you attempt to use the value of an uninitialized local variable. This helps you avoid dangerous execution-time logic errors. It's always better to get the errors out of your programs at compilation time rather than execution time.

3.5.2 AccountTest Class to Use Class Account (Cont.)

- ▶ The default value for an instance variable of type double is 0.0, and the default value for an instance variable of type int is 0.

3.5.2 AccountTest Class to Use Class Account (Cont.)

Software Engineering Observation 3.4

Replacing duplicated code with calls to a method that contains one copy of that code can reduce the size of your program and improve its maintainability.

3.5.2 AccountTest Class to Use Class Account (Cont.)

Fig. 3.10 | UML class diagram for Account class of Fig. 3.8.

3.6 (Optional) GUI and Graphics Case Study: Using Dialog Boxes

Location	Title—Exercise(s)
Section 3.6	Using Dialog Boxes—Basic input and output with dialog boxes
Section 4.15	Creating Simple Drawings—Displaying and drawing lines on the screen
Section 5.11	Drawing Rectangles and Ovals—Using shapes to represent data
Section 6.13	Colors and Filled Shapes—Drawing a bull's-eye and random graphics
Section 7.17	Drawing Arcs—Drawing spirals with arcs
Section 8.16	Using Objects with Graphics—Storing shapes as objects
Section 9.7	Displaying Text and Images Using Labels—Providing status information
Section 10.11	Drawing with Polymorphism—Identifying the similarities between shapes
Exercise 12.17	Expanding the Interface—Using GUI components and event handling
Exercise 13.31	Adding Java 2D—Using the Java 2D API to enhance drawings

Fig. 3.11 | Summary of the GUI and Graphics Case Study in each chapter.

```
1 // Fig. 3.12: Dialog1.java
2 // Using JOptionPane to display multiple lines in a dialog box.
3 import javax.swing.JOptionPane;
4
5 public class Dialog1
6 {
7     public static void main(String[] args)
8     {
9         // display a dialog with a message
10        JOptionPane.showMessageDialog(null, "Welcome to Java");
11    }
12 } // end class Dialog1
```

Fig. 3.12 | Using JOptionPane to display multiple lines in a dialog box.

```
1 // Fig. 3.13: NameDialog.java
2 // Obtaining user input from a dialog.
3 import javax.swing.JOptionPane;
4
5 public class NameDialog
6 {
7     public static void main(String[] args)
8     {
9         // prompt user to enter name
10        String name = JOptionPane.showInputDialog("What is your name?");
11
12        // create the message
13        String message =
14            String.format("Welcome, %s, to Java Programming!", name);
15
16        // display the message to welcome the user by name
17        JOptionPane.showMessageDialog(null, message);
18    } // end main
19 } // end class NameDialog
```
